

# \$10 Million Tuff “Pods” in the Dam Foundation

Todd N. Loar – Supervising Geological Engineer, CEG  
Association of Engineering Geologists  
September 2011 - Anchorage, AK

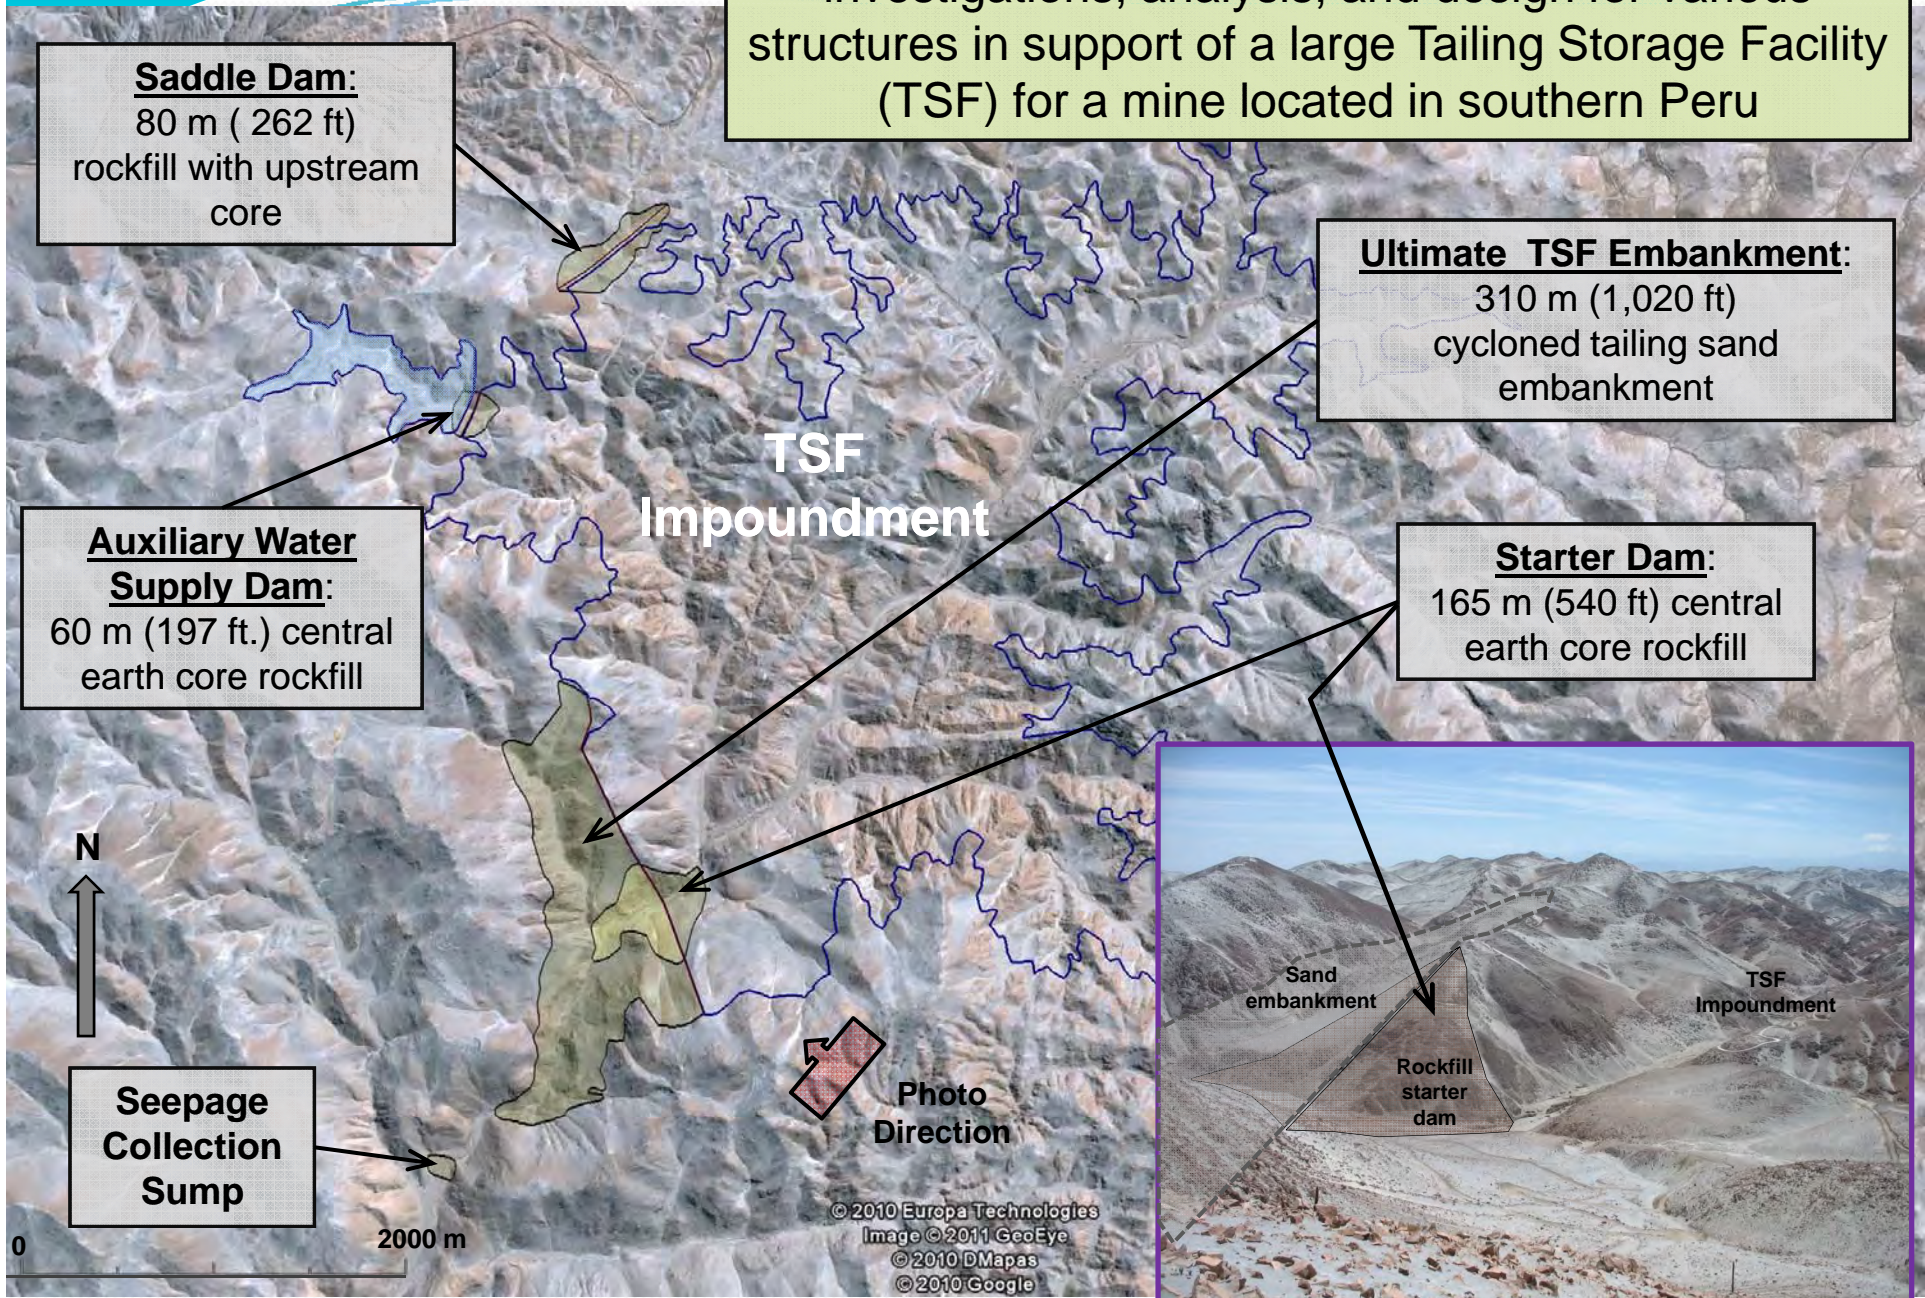

**MWH.**

BUILDING A BETTER WORLD

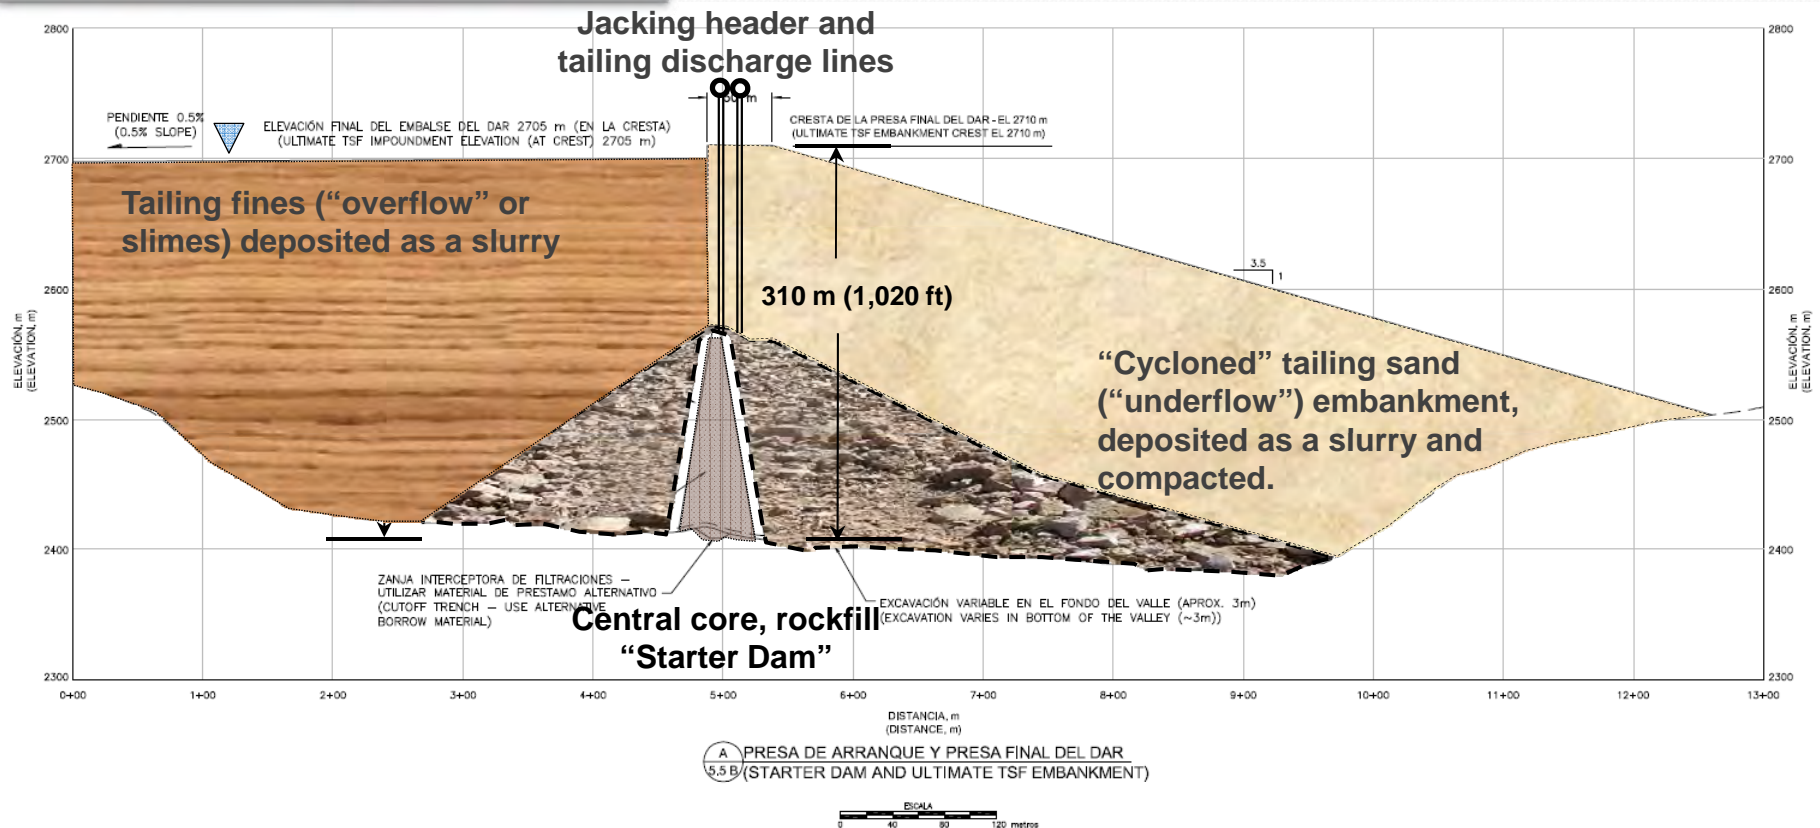

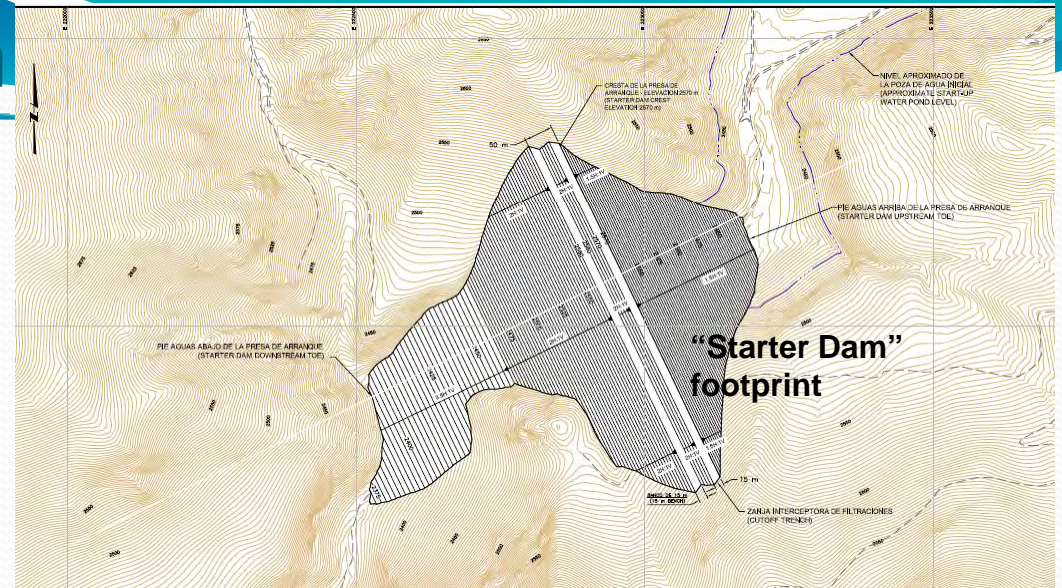

# Project Scope

MWH is currently providing final engineering investigations, analysis, and design for various structures in support of a large Tailing Storage Facility (TSF) for a mine located in southern Peru

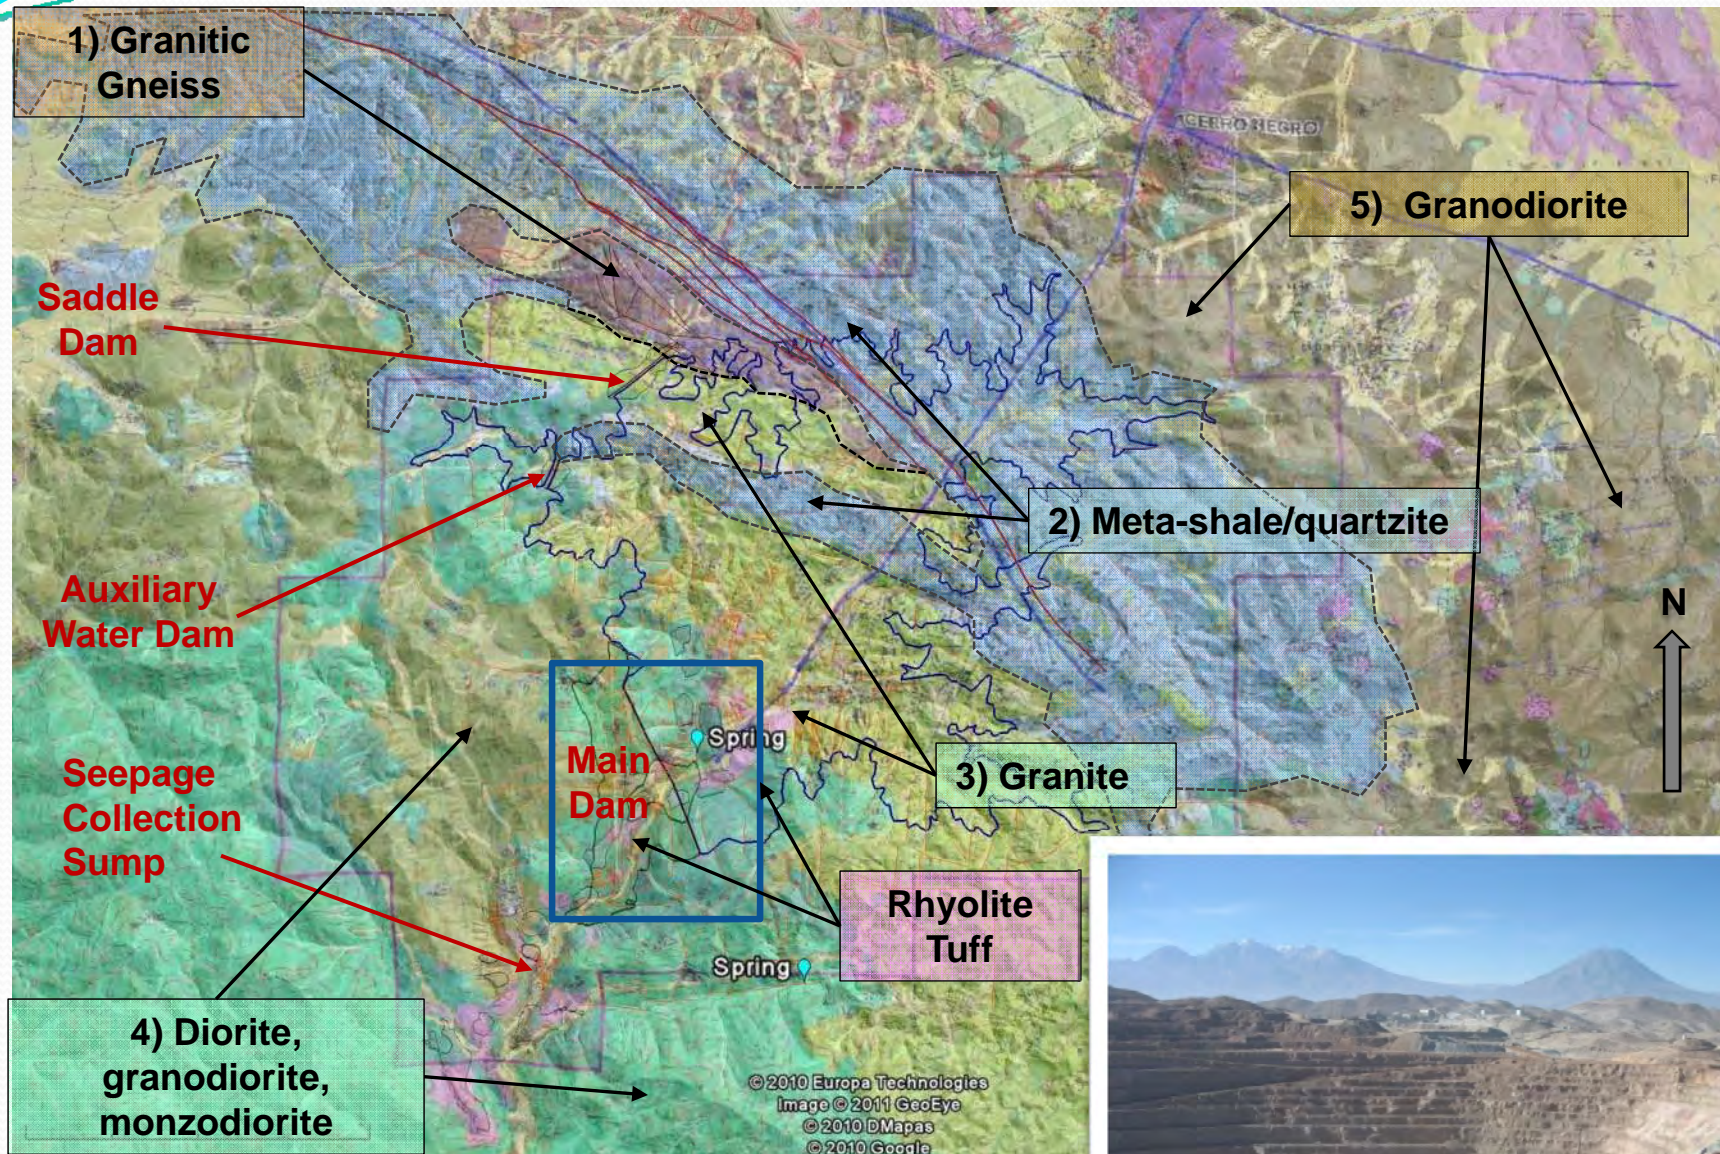

# TSF Configuration

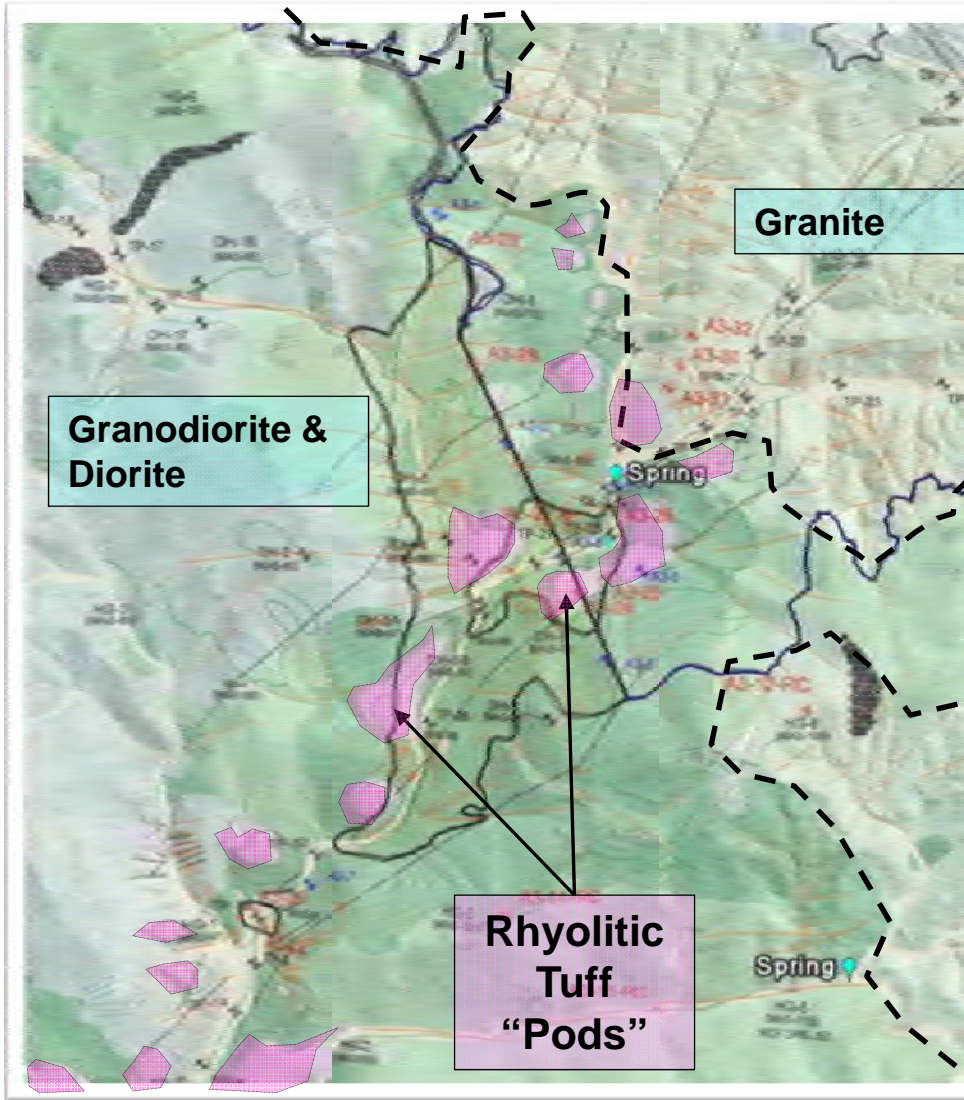

# Project Geologic Setting

# Geologic Site Conditions – Main Dam

## Site Conditions:

- ☐ Fractured granodiorite and diorite intrusive bedrock across the majority of the proposed foundation and most of the impoundment.
  - Generally high quality foundation conditions and permeability that improves with depth.
  - Faults/shears, hydrothermal alteration, and/or fracture zones in the main dam area and seepage collection sump.
- ☐ Spring near the upstream foundation toe (related to K contrast b/t Granite and Diorite).
- ☐ Gypsum infilling of fractures within the rock mass.
- ☐ **Rhyolitic Tuff "Pods" in the Starter dam and ultimate TSF Embankment footprint.**

# Rhyolitic Tuff Deposition

- 1 – Initially, ash accumulated in the in stream channels, swales, and on top of paleo-soil deposits and cooled quickly (may have been followed by a period of quiescence).
- 2 – Significant eruptive event resulted in thick pyroclastic accumulations (poorly welded tuff) along the stream channels, swales, and on top of the ash and/or paleo-soil deposits.
- 3 – Erosion removed the rhyolite tuff along the main stream channels resulting in discontinuous “pods” of this material left in place along the flanks of the valley slopes.

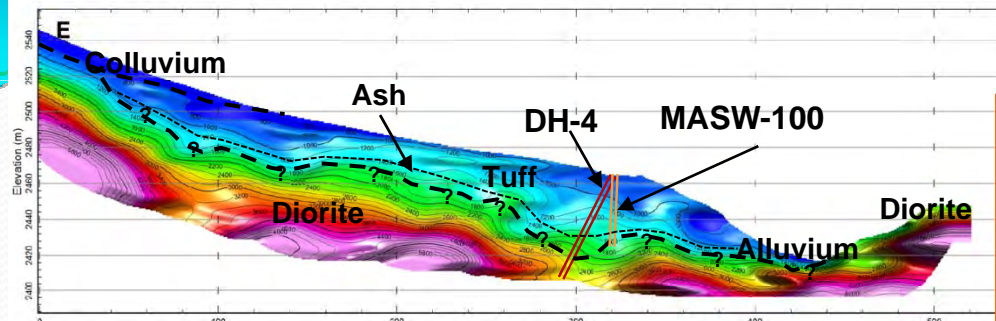

# Feasibility Level Field Investigations

- Identification and detailed mapping of the spatial extent of the “pods”.
- Test pits excavated around the tuff “pod” perimeters
- One (angled) drill hole to understand the geometry and engineering conditions of the “pods”

# Feasibility Level Field Investigations

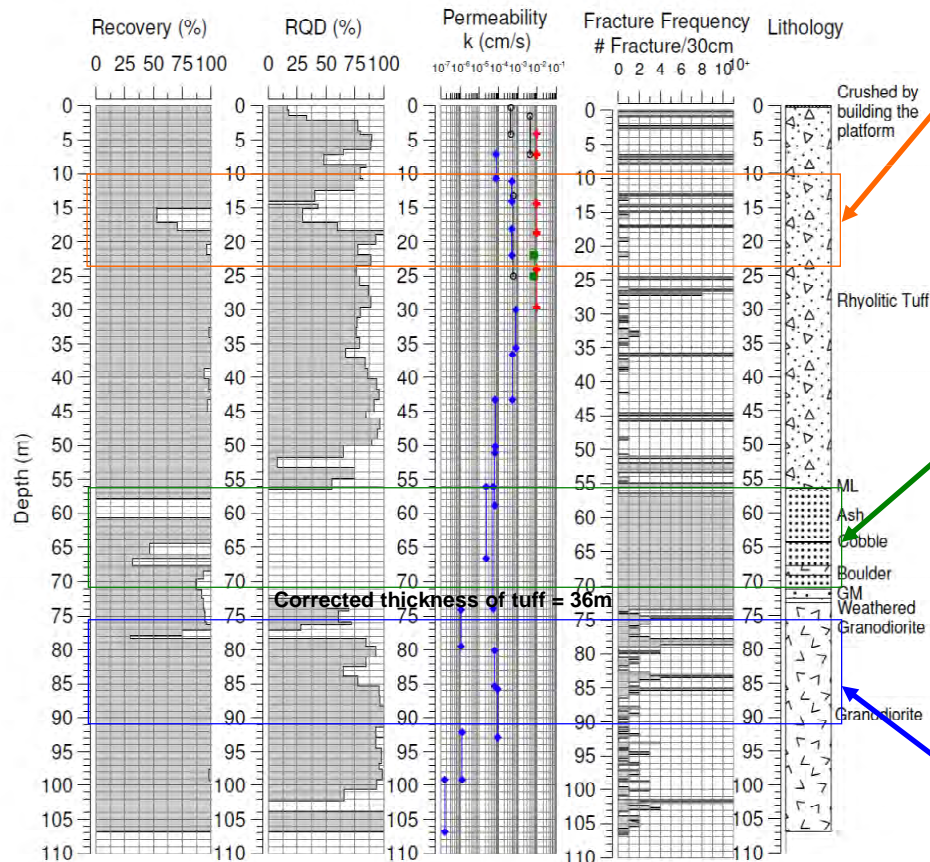

**Poorly welded rhyolitic lapilli tuff:** (weak (500 to 2000 psi), low density, high absorption and porosity, with open and continuous joint sets)

**Unwelded/friable ash**  
(silty sand / sandy silt (SM to ML), non-welded (friable and unconsolidated))

**Fractured diorite**  
(Generally highly permeable in the upper 5-10 m and then it gets tighter and higher quality with depth)

Note:

The depth shown is total drilled length.

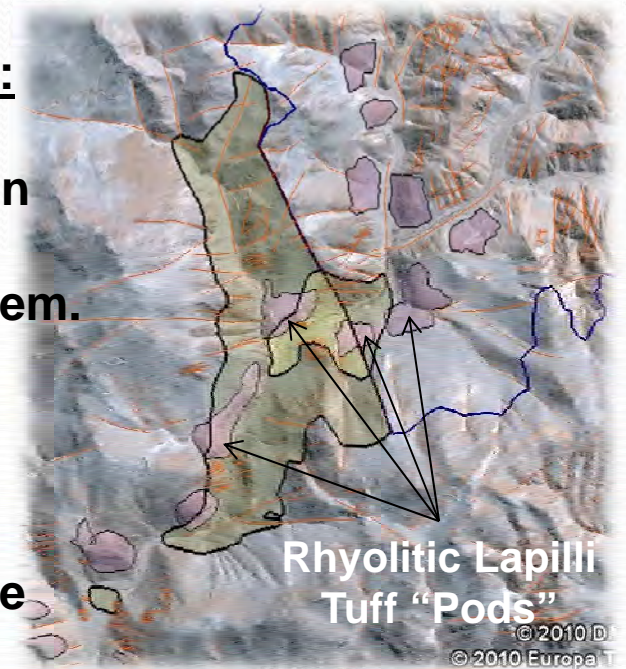

Groundwater Depth (m) / Approximate Elevation (m):  
10/10/08 - 82.492 / 2394.96

- Constant Head test interval
- ◆ Packer test interval
- Failed packer test interval: water returning to surface (Depict depth interval only; k is not calculated)
- + Packer test interval consumed the capacity of the pump (75 to 120 L/m)

# Technical Considerations/Constraints

- **Potential seepage pathway through or under “pods”:**
  - Pods are discontinuous U/S–D/S, however:
    - Irregular seepage gradients in the foundation
    - Piping of the underlying ash layer, or
    - Contamination/plugging of under-drain system.
- **Potential liquefaction at base:**
  - The underlying, fine grained silty sand (SM) ash could potentially liquefy under seismic loading resulting in settlement or deformations under the dam.
- **Potential slope instability:**
  - Ash layer could represent a basal slip surface and stability issues may develop due to loading and saturating of basal contact.
- **Potential collapse or differential settlement:**
  - Uncertainty about the ash response due to loading and saturation (i.e. collapsibility of air-fall type deposits)

# Estimated Removal Costs

- ❑ Very costly to fully remove the pods
- ❑ Material is not useable (i.e. weak, low def. modulus, porous, unacceptable for rockfill, aggregate, or filters)
- ❑ Limited space for additional disposal
- ❑ Significant delays relating to construction schedule
- ❑ Is it possible to leave all or partial tuff pods in place under the TSF Embankment?

**The extent, geometry, and engineering properties of the rhyolite tuff and ash must be characterized in the pods located in the area of the Main Dam.**

# Final Design Level Field Investigations

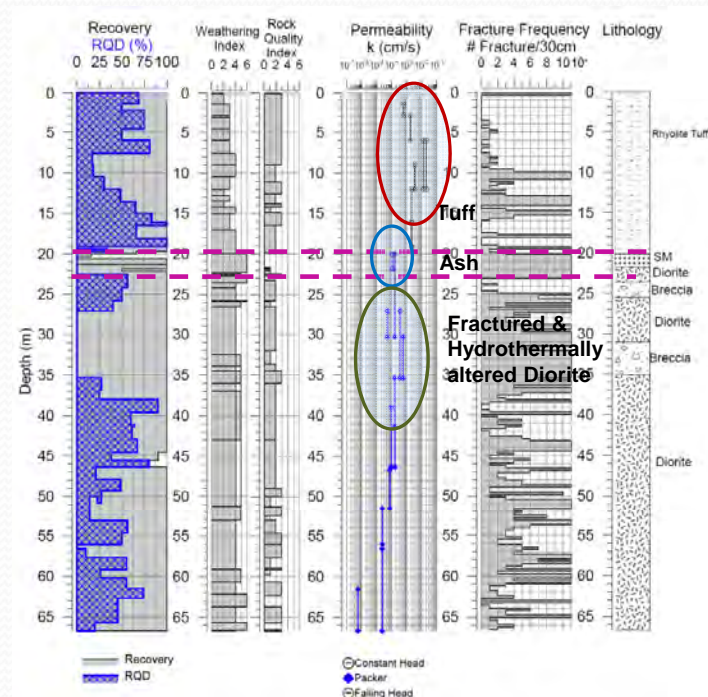

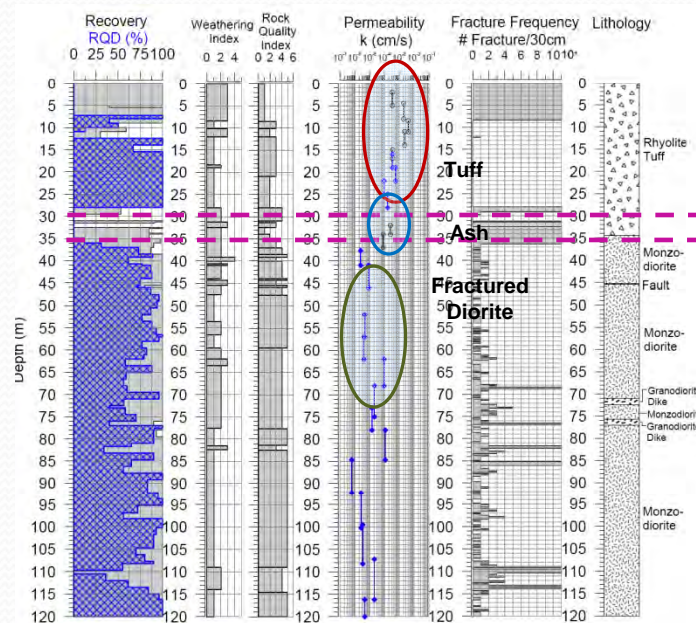

- ❑ Additional drilling
  - HQ core
- ❑ In-situ testing
  - SPT, MC, water pressure testing
- ❑ Test pits
  - sand cones
- ❑ Geophysics
  - refraction, MASW
- ❑ Lab testing
  - strength, consolidation, index properties, XRD

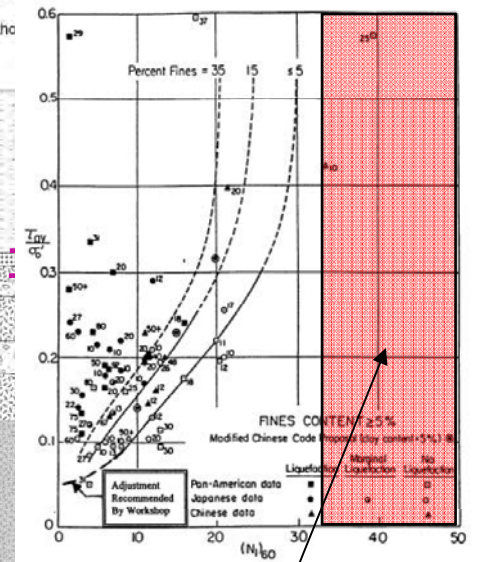

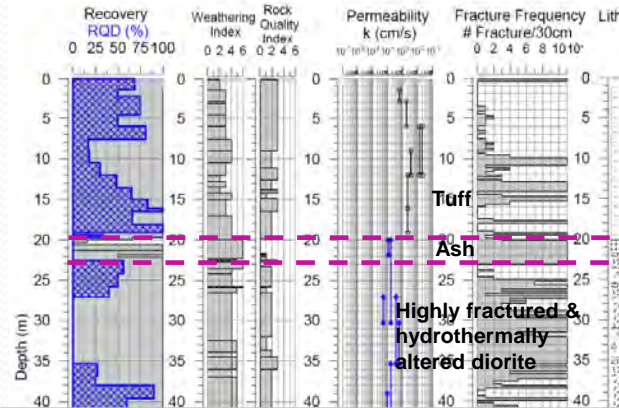

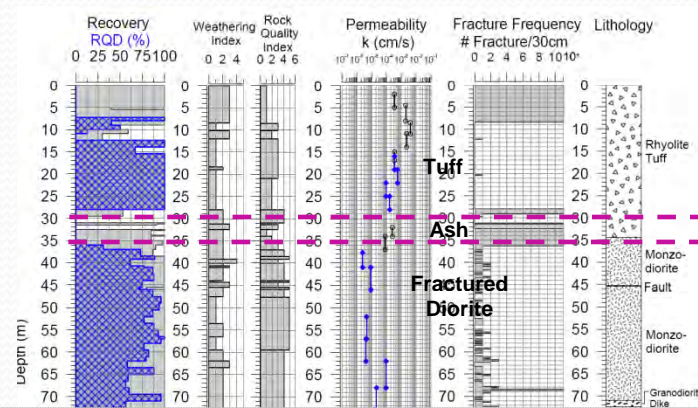

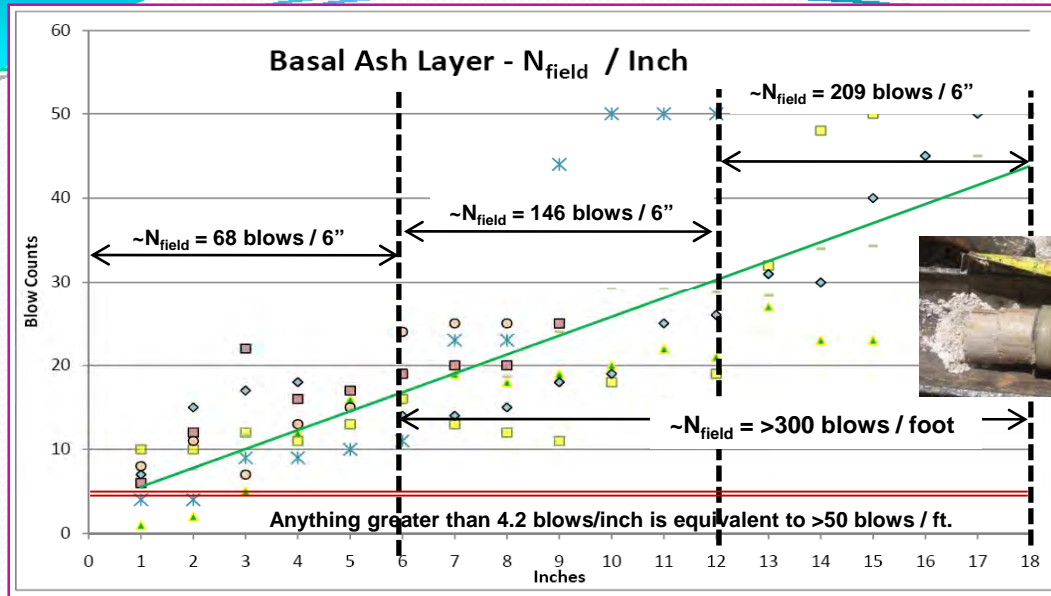

# Drill Data

- Tuff:  $2.5 \times 10^{-3}$  cm/sec (high)
- Basal ash layer:  $1 \times 10^{-4}$  cm/sec
- Underlying upper fractured diorite (to about 5 m):  $5 \times 10^{-4}$  in near surface, highly fracture zones.

# Drill Data

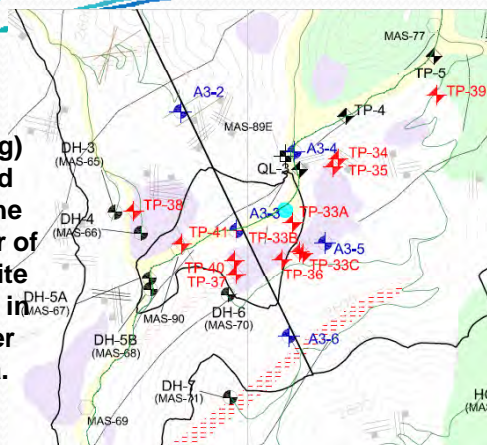

- Drill/SPT data results of suggest material at base is very/extremely dense (hard) and is not likely to collapse.
- SPT data indicates a relative strength of  $\phi = 35^\circ$  to  $40^\circ$ .
- Liquefaction potential of basal ash layer is considered to be extremely low (i.e. non-liquefiable).

Range of SPT- $N_{1(60)}$  values in ash  $\gg 30$ .

# Test Pits & Material Characterization

**Test pits (hand dug) excavated around the perimeter of the rhyolite tuff pods in the starter dam area.**

## In-situ - Sand Cone Densities of Unwelded Ash in Test Pits

Test Pit ID	Wet Density (g/cm³)	Moisture Content (%)	Dry Density (g/cm³)
TP-33b	1.49	0.50%	1.48
TP-34	1.46	0.40%	1.45
TP-35	1.40	1.30%	1.38
TP-40	1.47	1.30%	1.45
TP-41	1.38	0.60%	1.37
<b>Average w/o TP-36</b>	<b>1.44</b>	<b>0.82%</b>	<b>1.43</b>

## Lab - Relative Density Tests (Sand Cone Material)

Trial	Min Densities		Max Densities	
	(pcf)	(g/cm³)	(pcf)	(g/cm³)
1	67.76	1.085	91.02	1.458
2	68.23	1.093	90.81	1.455
3	67.83	1.086		
<b>Average</b>	<b>67.94</b>	<b>1.09</b>	<b>90.92</b>	<b>1.46</b>

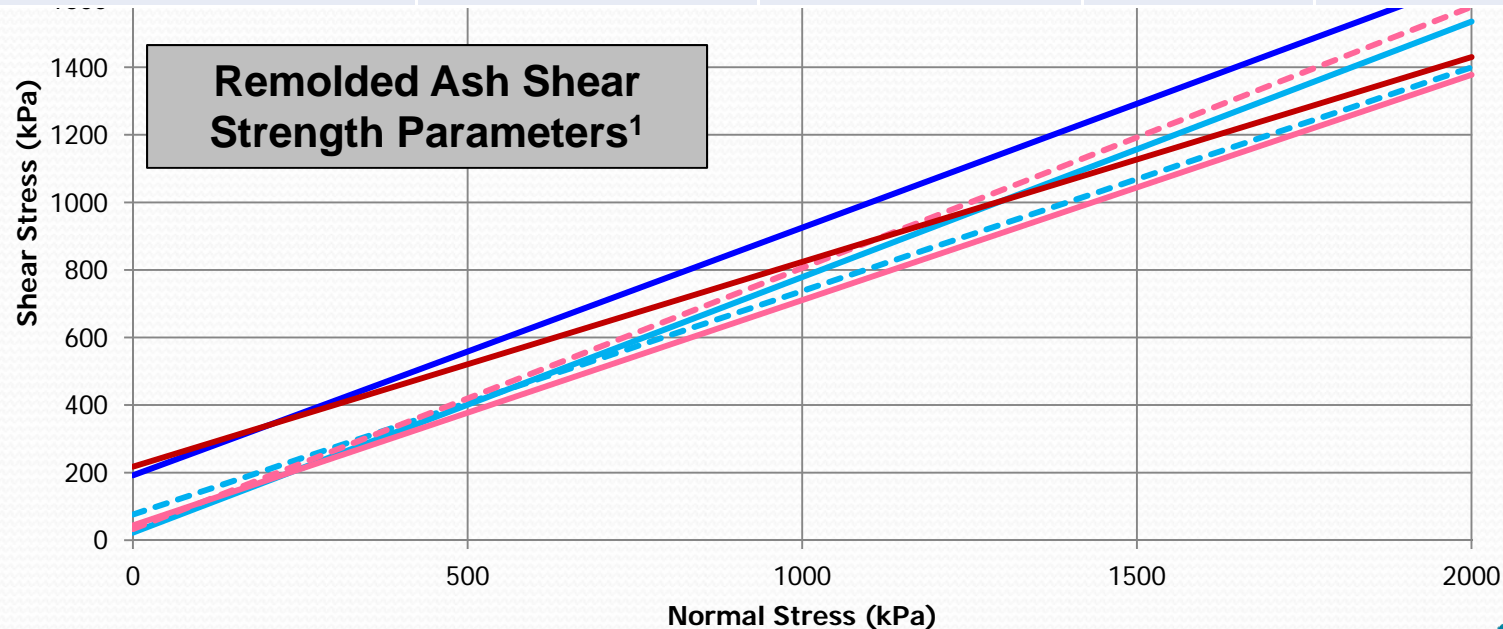

## Targeted “Remolded” Densities for Shear Strength Tests

Target Density (g/cm³)	Relative Density	Description
1.40	≈95%	Field Sand Cone Density, Very Dense
1.30	≈90%	Medium Dense

# Test Pits & Material Characterization

Density (g/cm <sup>3</sup> )	Test	Condition	c' (kPa)	Φ'
1.30 (90%)	Direct Shear	Dry	33	38°
1.30 (90%)	Direct Shear	Saturated	44	34°
1.29 (88%)	CU Triaxial	Saturated	218	31°
1.39 (95%)	Direct Shear	Dry	76	34°
1.39 (95%)	Direct Shear	Saturated	23	37°
1.37 (94%)	CU Triaxial	Saturated	192	36°

1) potentially “destroys” the pre-existing granular structure in remolded soil testing – currently we are testing ash collected from MC liner samples at UC Berkeley)

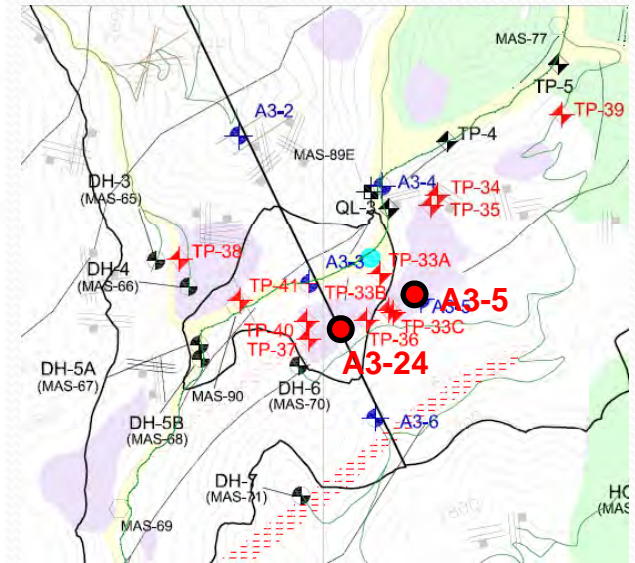

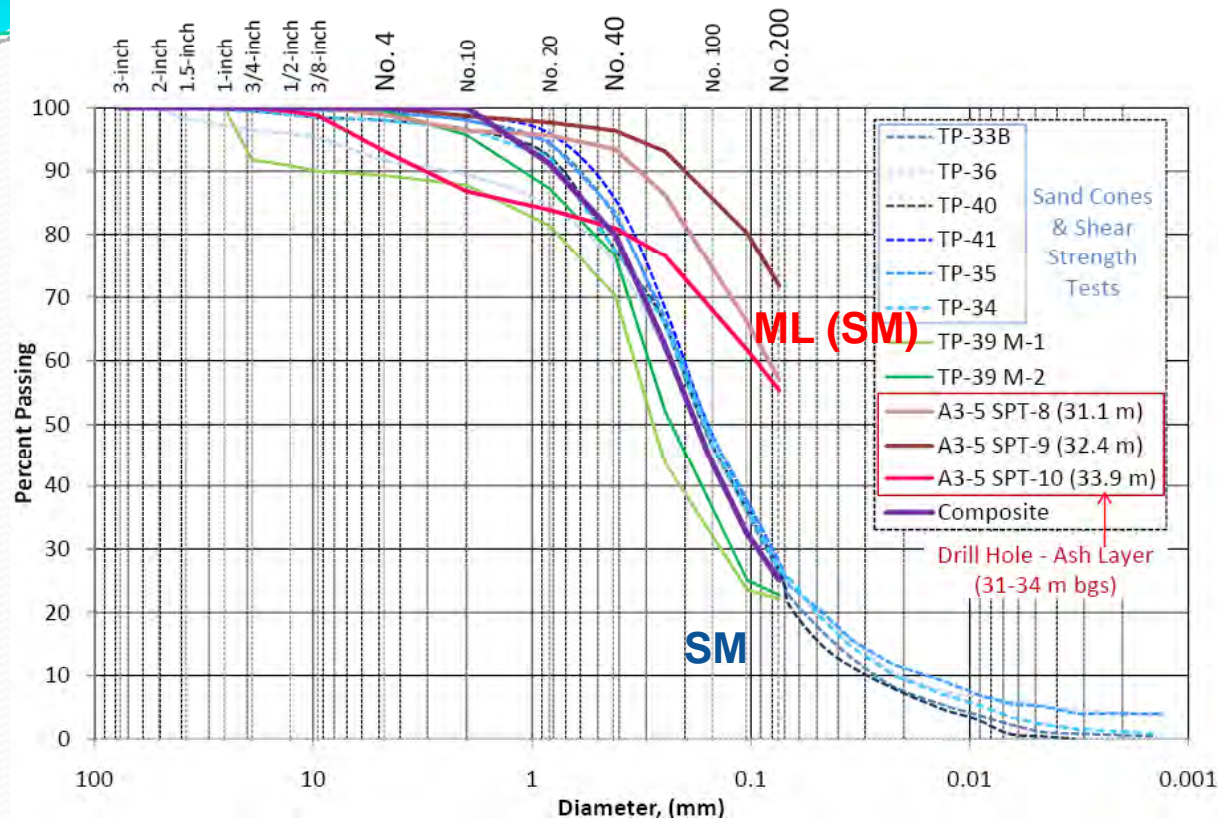

# Test Pits & Material Characterization

Currently we are performing consolidation/collapse testing on additional tuff samples

# Test Pits & Material Characterization

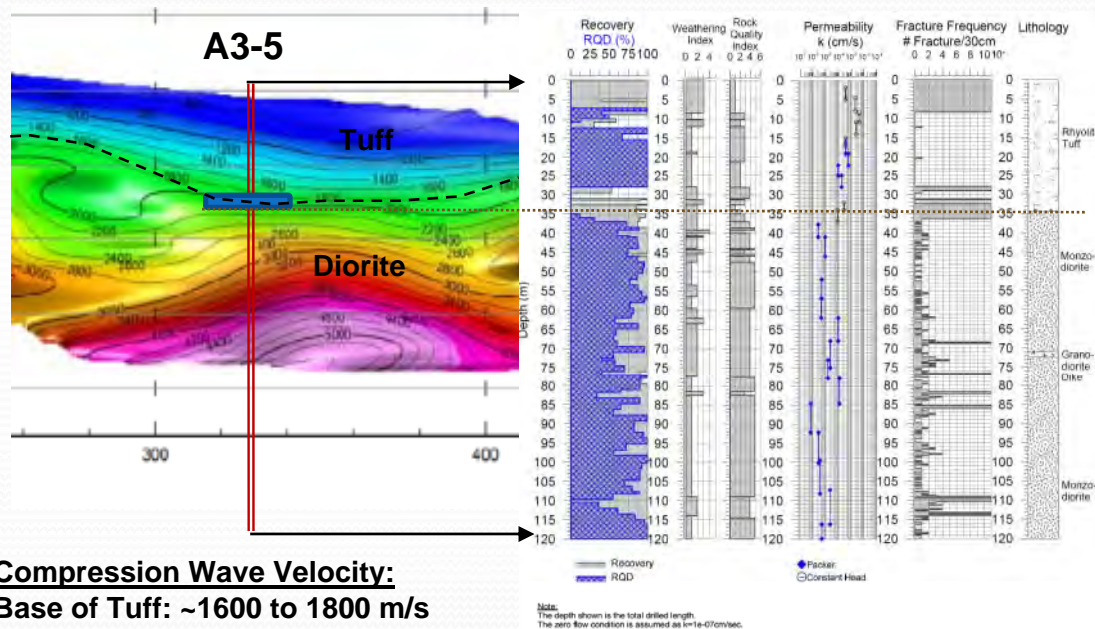

**SM** material collected from **test pits** excavated around the perimeter of the pods

**ML (SM)** material collected from drill hole **A3-5** and **A3-24** (additional results pending)  
 samples collected from ash under the middle portion of the tuff “pod”

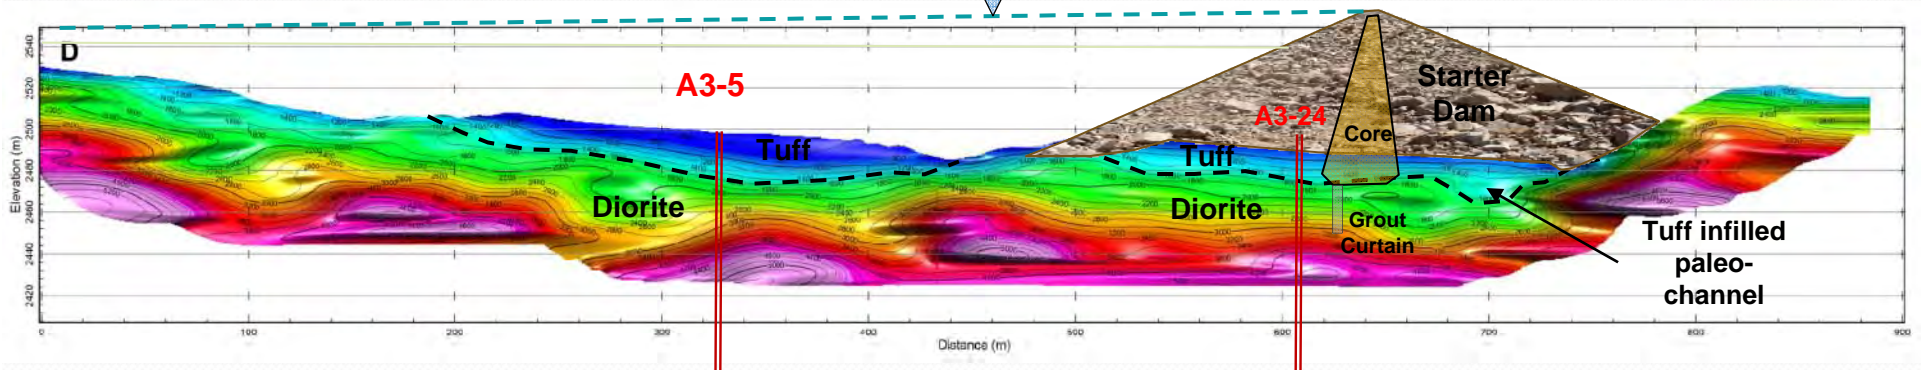

- Consolidation/collapse and grain crushing has already occurred.
- Washing out of fines from the perimeter.
- Weathering and mineral degradation is greater internally under the pod

# Geophysics (Refraction & MASW)

**Compression Wave Velocity:**  
 Base of Tuff: ~1600 to 1800 m/s  
 Diorite: >2000 m/s

View is looking uphill, to the SE

# Stability & Seepage Modeling

View of 3-D stability and deformation model looking downstream

We are currently in the process of performing additional stability and seepage analysis for the overall structure and optimization of the design geometry.

# Final Design

## Preliminary Findings – Tuff “Pods”

- ❑ Poorly-welded rhyolite tuff “pods” are 20 to 50 m thick and underlain by a 20 cm to 2 m thick layer of unconsolidated (un-welded) ash classified as a silty fine sand (SM) to sandy silt (ML).
- ❑ The poorly welded tuff has very high hydraulic conductivity along open and continuous fractures.
- ❑ The ash has a lower hydraulic conductivity than the overlying tuff and the underlying fractured diorite (a potential barrier to seepage along the base).
- ❑ “Pods” are discontinuous. (But irregular/undesirable seepage gradients could be realized if left in place around the core).
- ❑ Ash is very dense.
- ❑ There is a low potential for liquefaction of the underlying ash layer.
- ❑ Tuff and ash are consolidated with a low potential for additional consolidation/collapse or differential settlement.

# Final Design

## Preliminary Findings – Tuff “Pods”

- 1 - Tuff and ash must be completely excavated from below the core and filters/transitions.
- 2 – Additional seepage/stability modeling could show that there is little risk with leaving the tuff “pod” A under the main embankment alignment. However, at this time we are recommending removal of this “pod”.
- 3 - The upper 3 m of the tuff “pods” under the Main TSF sand embankment should be removed, but otherwise left in place under the dam.

# Questions & Discussion
